(54) Title: **DIGITAL RIGHTS MANAGEMENT**

(57) Abstract: Digital rights (110) are associated with a semi-unique node identifier obtained or calculated from characteristics of a mobile device (302) attached to a consumer device, rather than with the node identifier of the consumer device itself (106, 206). The user of the consumer device (106, 206) may access the digital rights management encrypted content (which may come from local persistent storage or a network) by attaching the mobile device (302) to the consumer device (106, 206). In this way, the rights can be associated with the node identifier of the mobile device (302), and the rights are thus usable for the consumer device to access the encrypted content.

DIGITAL RIGHTS MANAGEMENT

The present invention is in the field of digital rights management (DRM). The present invention has particular applicability to node locking in the context of mobile devices.

If there is to be a viable commerce based upon the electronic distribution of valuable multimedia content (such as for example reports, images, music tracks, videos, etc.), then there must be some means of enforcing and retaining copyright control over the electronic content. There is now emerging a set of hardware and software solutions, generically known as digital rights management (DRM) solutions, that aim to provide this copyright control while, to a varying degree, also enabling new commercial models suited to the Internet and electronic delivery. Common to virtually all these solutions is the requirement that the multimedia content files be distributed within a persistent tamperproof encryption wrapper (the idea being that a million copies of encrypted content is no more valuable than one). Very simply, DRM works by carefully providing the consumers of this encrypted content with secret decryption keys that provide temporary access to the content for some controlled purpose, e.g. viewing, printing, playing, etc. without ever providing access to the raw decrypted content that could be used for unauthorised reuse or redistribution.

Figure 1 illustrates schematically an overview of how typical DRM systems work. Referring to Figure 1, a "publisher" of digital content seals their digital content files, buffers or streams within a layer of encryption and

-2-

digital signatures into a DRM-encrypted content format 102. The encryption makes it difficult for malicious consumers to obtain access to the raw decrypted content (and make unauthorised copies for redistribution). The digital  
5 signatures prevent malicious consumers from tampering with the encrypted content format (perhaps to pass off the content as their own) by enabling the DRM system to detect the smallest change to the encrypted content. The DRM-encrypted content 102 can then be delivered to consumers  
10 via any electronic distribution medium 104, e.g. web, ftp, email, CD-ROM, etc. The publisher need not worry about protecting the DRM-encrypted content 102 in transit to the consumer since it is inherently protected by its encryption layer and digital signatures.

15

Less sophisticated DRM systems sometimes bundle individual consumer access rights with the content, either within the encryption layer or at least protected by the digital signatures. The advantage of bundling rights with  
20 the content is that the consumer can obtain both the content and the rights at the same time. Disadvantages include extreme inflexibility in the rights management policies that can be implemented and an enormous versioning problem (since there needs to be a separate version of the  
25 encrypted content file 102 for each consumer and a new version of the encrypted content whenever the rights change):

More sophisticated DRM systems deliver the rights  
30 separately from the content (from a DRM server 108). The rights are encoded in some electronic format 110 (i.e. electronic "rights") and specify the permitted relationship between consumers and DRM-encrypted content sets (and

-3-

subsets), e.g. which content the consumer can access, what they are permitted to do with it (e.g. printing), and for how long.

5       A specialised viewer (the DRM client 106) resident on the consumer device is required to obtain, manage and interpret the rights, temporarily decrypt the encrypted content and view/play it within a secure environment (so that the consumer cannot obtain access to the raw decrypted  
10 content or the decryption keys) subject to the restrictions implied by the consumer's rights (e.g. view but do not print a document). The DRM server 108 is responsible for issuing rights to requesting DRM clients 106. Current DRM systems typically issue rights to authenticated consumers  
15 at the time of purchase (or grant) and the rights are transferred to permanent storage on the consumer device 106. The DRM server 108 plays no further role in the ongoing use of those rights.

20       In general, "content sets" can be thought of as a related set of one or more digital content files, buffers or streams. In general, "rights" can be thought of as an electronic description (explicit or by implication) of the association between consumers (or consumer devices) and  
25 DRM-protected content sets. Rights can optionally specify means of identifying the consumer (or consumer device) to which the rights "belong"; means of identifying the content sets and subsets to which the rights apply; encryption keys and checksums (cryptographic or otherwise); and the  
30 specific access rights granted to the consumers (and/or their consumer devices) over those content sets (e.g. whether or not the consumer can print a document, the duration of access, etc.). Rights can be encoded in any

-4-

machine-readable form (e.g. parsable languages, specialised data structures, etc.) and are used internally by the DRM system to grant, deny or meter consumer access to encrypted content. In general, "node locks" can be thought of as  
5 rights that are tied to a particular consumer device or "node", i.e. rights that will only provide access to DRM-encrypted content on one particular consumer device.

It is preferable for a DRM system to issue rights to a  
10 consumer for the shortest possible time: the rights are preferably issued at the time the consumer actually attempts to access the encrypted content and preferably removed from the consumer device as soon thereafter as possible. In preferred implementations, this implies that  
15 the rights are stored on a remote server hosted on a network (e.g., the Internet or an intranet). The consumer identifies herself to the local DRM system which transparently opens network connections to the remote server to obtain the rights which are then used to decrypt  
20 and access the encrypted content.

One problem with issuing rights at the time of access attempt is that many consumers may not have an Internet (or intranet) connection at the time they wish to access the  
25 encrypted content, perhaps due to being on a flight with a laptop computer onto which encrypted content has been downloaded. If the rights are stored on a remote networked server, the consumer in this case (for flights lacking network connections) cannot connect to the DRM server and  
30 therefore cannot access the encrypted content. This lack of guaranteed Internet (or intranet) access has led many DRM solution providers to store the consumer's rights on the fixed or removable disk drives of the consumer device.

-5-

Storing the rights on the consumer device, however, creates another drawback in that it becomes trivial for the consumer to redistribute the stored rights on to other consumers and therefore defeat the basic copyright protection of the DRM system.

In order to overcome this drawback, typical DRM solutions that store the rights on the consumer device implement a "node-lock", i.e. rights that are somehow tied to the consumer device and cannot therefore be usefully copied to another device. Figure 2 illustrates schematically the basic "node-lock" concept in the context of consumers attempting to access DRM-encrypted content on two consumer devices 106 and 206 (for example, personal computers). The assumption is that there are DRM clients installed on both consumer devices 106 and 206 and that the DRM-encrypted content is either stored locally or obtained from a network. In order to obtain access to DRM-protected content on consumer device 106, the locally installed DRM client obtains rights 110 from a remote DRM server 108. As part of the DRM transaction, those rights 110 are "locked" to a pseudo- or semi-unique node identifier obtained or calculated from characteristics of consumer device 106. The "locked" rights 106 are then stored in persistent storage belonging to consumer device 106. Subsequent use of the locally stored rights 110 involve the DRM client on consumer device 106 re-obtaining or re-calculating the node identifier of consumer device 106 and checking that it matches the value to which the rights 110 were originally locked. Transferring the "node-locked" rights to persistent storage on consumer device 206 renders them ineffective since, depending upon the nature of the node identifier, there is very little chance that the DRM client

-6-

on consumer device 206 will obtain or calculate a node identifier (for consumer device 206) that matches that of the transferred rights (which are locked to the node identifier of consumer device 106).

5

Thus, a disadvantage with node-locked rights is that the consumer is now restricted to accessing the DRM-encrypted content on one (or at most a few) consumer devices. This is increasingly bothersome as consumers  
10 become increasingly mobile and migrate between business desktop machines, laptops, palmtops and home computers. The increasing availability of network-enabled computers, any of which can be used to access Internet or intranet hosted services, makes simple node-locking closely resemble  
15 the much despised PC copy-lock software protection schemes.

What is desired, then, is to extend the concept of node locking to account for an increasingly mobile consumer community.

20

According to a first aspect of the present invention, there is provided a digital rights management (DRM) system governing whether DRM-protected content can be rendered on a content rendering device; wherein at least one rights  
25 specification governing access to DRM-protected content on the content rendering device is tied to a first node identifier that is based on a characteristic of a mobile device coupleable to the content rendering device, the system comprising: a DRM client arranged to operate within  
30 the content rendering device and which has access to the at least one rights specification governing access to the DRM-protected content; wherein the at least one rights specification is restricted to apply to at least one node

-7-

identifier; the DRM client being arranged to retrieve said characteristic of a mobile device coupleable to the content rendering device, to generate the first node identifier based on said characteristic, and to check that the first  
5 node identifier matches the or at least one node identifier to which the at least one rights specification is restricted; herein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification available to the DRM client  
10 and subject to the first node identifier matching the or at least one node identifier to which the at least one rights specification is restricted.

According to a second aspect of the present invention,  
15 there is provided a method of accessing digital rights management (DRM) protected content for rendering by a content rendering device, wherein at least one rights specification governing access to the DRM-protected content on the content rendering device is tied to a first node  
20 identifier that is based on a characteristic of a mobile device coupleable to the content rendering device, the at least one rights specification being restricted to apply to at least one node identifier, the method comprising the steps of: retrieving from a mobile device coupled to the  
25 content rendering device said characteristic of the mobile device coupled to the content rendering device; generating the first node identifier based on said characteristic; and, checking that the first node identifier matches the or at least one node identifier to which the at least one  
30 rights specification is restricted; wherein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification available to the DRM client and subject to the first node

- 8 -

identifier matching the or at least one node identifier to which the at least one rights specification is restricted.

According to a third aspect of the present invention,  
5 there is provided a digital rights management (DRM) system governing whether DRM-protected content can be rendered on a content rendering device, wherein at least one rights specification governing access to DRM-protected content on the content rendering device is obtained from a mobile  
10 device coupleable to the content rendering device, the system comprising: a DRM client arranged to operate within the content rendering device that is to retrieve from the mobile device the at least one rights specification applying to the DRM-protected content which the content  
15 rendering device is attempting to render; wherein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification obtained by the DRM client from the mobile device.

20

According to a fourth aspect of the present invention, there is provided a method of accessing digital rights management (DRM) protected content for rendering by a content rendering device, wherein at least one rights  
25 specification governing access to DRM-protected content on the content rendering device is obtained from a mobile device coupleable to the content rendering device, the method comprising the steps of: retrieving from the mobile device the at least one rights specification applying to  
30 the DRM-protected content which the content rendering device is attempting to render; wherein access to the DRM-protected content by the content rendering device is

-9-

granted subject to the at least one rights specification obtained from the mobile device.

According to a fifth aspect of the present invention,  
5 there is provided a digital rights management (DRM) system for managing access to content on a content rendering device that is coupled to a wireless device that is coupled to a wireless network, wherein usage of the wireless device on the wireless network produces billing information that  
10 is accounted for by a billing system, the system comprising: a DRM server for coupling to a said wireless network and arranged to provide at least one rights specification for gaining access to content on a said content rendering device, the DRM server being arranged to  
15 account for usage of the DRM-protected content and to provide billing information based on the usage of the DRM-protected content to a said billing system, such that the said billing system can consolidate billing information based on the usage of the DRM-protected content with  
20 billing information based on the usage of the wireless device.

In accordance with one preferred embodiment of the present invention, rights are associated with a pseudo- or  
25 semi-unique node identifier obtained or calculated from characteristics of a mobile device attached to a consumer device, rather than with the node identifier of the consumer device itself. The user of the consumer device may access the DRM-encrypted content (which may come from  
30 local persistent storage or via a network) by attaching the mobile device to the consumer device. In this way, the rights can be associated with the node identifier of the

-10-

mobile device, and the rights are thus usable for the consumer device to access the encrypted content.

Embodiments of the present invention will now be described by way of example with reference to the accompanying drawings, in which:

Figure 1 illustrates schematically an overview of a prior art DRM approach;

10

Figure 2 illustrates schematically limitations of prior art node locking;

Figure 3 illustrates schematically an example of an embodiment in accordance with the present invention for mobile device lock authentication;

15

Figure 4 illustrates schematically a variation the Figure 3 embodiment, whereby the rights are stored on the mobile device used for authentication;

20

Figure 5 illustrates an example of mobile device lock authentication making use of a wireless network in accordance with an embodiment of the present invention; and,

25

Figure 6 illustrates an example of mobile device lock authentication making use of smart cards in accordance with an embodiment of the present invention.

30

Referring first to Figure 3, this figure illustrates schematically an embodiment of the present invention that is similar to the conventional node-locked solution

-11-

illustrated in Figure 2. However, in accordance with the Figure 3 embodiment of the invention, the rights 110 are associated (as part of the transaction with the DRM server 108) with a semi-unique node identifier obtained or  
5 calculated from characteristics of a mobile device 302 attached to a consumer device 106 (e.g. a personal computer), rather than with the node identifier of the consumer device 106. Note that DRM server as referred to herein refers to just DRM server software or both DRM  
10 server software and hardware. Thus, the user of the consumer device 106 may access the DRM-encrypted content (which may come from local persistent storage 202 or the network) by attaching the mobile device 302 to the consumer device 106. In this way, the rights 110 can be associated  
15 with the node identifier of the mobile device 302, and the rights 110 are thus usable for the consumer device 106 to access the encrypted content.

The consumer device 106 may be, for example, a  
20 personal computer, a set-top box or any other consumer device not typically carried on a consumer's person. The mobile device 302 may be, for example: a palmtop (e.g. Palm Pilot) computer, a cellular phone, a portable audio device, or other mobile device. In one embodiment, the  
25 mobile device is a mobile communications device having means by which the mobile device can connect to a telecommunications network, such connection being optionally wireless or cabled. Some form of consumer identity can be deduced from each of these devices, e.g.  
30 the telephone number of the mobile telephone, a synchronisation id or email address from the palmtop or a security id from a portable audio device. In this embodiment, a new type of node-locked rights is stored on

-12-

the consumer device, one that is tied to the mobile device attached to the consumer device rather than to the consumer device itself. The new type of rights contain some information about the mobile device and can only be used by  
5 the local DRM solution if it can verify (preferably via some electronic challenge and response protocol with the mobile device) that the correct mobile device is attached to the consumer device.

10 In another embodiment, the rights locked to the mobile device can only be used by the local DRM solution within a configurable time period of it last verifying (via some electronic challenge and response protocol with the mobile device) that the correct mobile device was attached to the  
15 consumer device, so that the mobile device does not need to be permanently connected to the consumer device.

Advantages of this new type of node-locked rights include (a) that the consumer can now access encrypted  
20 content on any device to which the mobile device can be attached; (b) that the consumer cannot easily make copies of the mobile device and thereby defeat the DRM solution; (c) that the consumer no longer requires a network connection once the rights are stored on the consumer  
25 device; (d) mobile devices are inherently less vulnerable to tampering than many consumer devices, e.g. personal computers.

In accordance with further embodiments, as illustrated  
30 in Figure 4, the rights 110 are stored in the persistent storage (e.g. non-volatile RAM) of the mobile device 302 itself, as such devices are routinely coupled to consumer devices (e.g. personal computers) such that the storage in

-13-

the mobile device is accessible to the consumer device.

For example, mobile telephones are connectable to personal computers in order to provide the personal computer with a wireless data modem connection. Palmtop computers are

5 connectable to personal computers to synchronise email, contact and scheduling information. Portable audio players (e.g. portable MP3 players) are connectable to personal computers for transferring audio tracks downloaded from the Internet to the portable device.

10

Some form of consumer identity can be deduced from each of these devices, e.g. the telephone number or network address of the mobile telephone, a synchronisation id or email address from the palmtop computer, or a security id  
15 from a portable audio device. In addition, each of these devices has some form of persistent on-device storage, e.g. SIM cards on mobile telephones, battery-backed RAM on palmtop computers, flash RAM on portable audio players. The rights stored in the persistent on-device storage in this  
20 embodiment may include some information about the mobile device, and the rights can only be used by the local DRM solution if it can be verified (by, for example, some electronic challenge and response protocol with the mobile device) that the rights are stored on the correct mobile  
25 device attached to the consumer device, using the node identifier obtained or calculated from characteristics of the mobile device. In similar but alternative embodiments, the rights 110 are stored on a removable secondary storage medium (capable of being read by either the consumer device  
30 or the mobile device) such as a floppy disk or a removable memory card or pack.

-14-

In another embodiment, the rights obtained from the mobile device can only be used by the local DRM solution on the consumer device within a configurable time period of it last verifying (via some electronic challenge and response  
5 protocol with the mobile device) that the mobile device from which the rights were obtained was attached to the consumer device, so that the mobile device does not need to be permanently connected to the consumer device.

10 In accordance with further embodiments, discussed with reference to Figure 5, wireless network capabilities are used to enhance the effectiveness of a mobile device locking solution. There is a trend to unify wireless network capabilities with mobile computing devices (whether  
15 general purpose or special purpose computing devices). As discussed above, these mobile devices typically provide reasonable verification that the holder of the device is an authorised rights user, because wireless mobile devices must have a unique network address (such as a telephone  
20 number) in order to route communication traffic to/from the wireless mobile device and this address is closely tied to the holder of the device. Furthermore, mobile telephones already make periodic communication to a local cell (designated by reference numeral 502 in Figure 5) and are  
25 inherently networked devices.

In accordance with these further embodiments, the wireless connection (either using on-demand dial-up connections or via the background cell communications) is  
30 used for obtaining, refreshing or relinquishing rights to/from a remote DRM server. In practical DRM applications, DRM clients must obtain rights from a DRM server, may sometimes refresh (effectively re-request)

-15-

those rights from a DRM server in order to prevent them relapsing to the DRM server and being issued to other DRM clients, and may relinquish those rights back to a DRM servers when they are no longer required (so that they may  
5 be issued to other DRM clients). The wireless connection can also be used to obtain a trusted clock signal from a central server (not necessarily the DRM server) which can be used to reliably control start and stop times for DRM-managed access. Such control is reliable because the clock  
10 obtained from for example the cellular system is a trusted clock (as opposed to a clock on the computing device that can often be manipulated by the user). Furthermore, the wireless connection can also be used to send auditing information to a central server for reporting and/or  
15 billing of use of DRM-protected content. In addition, mobile telephones already have established billing channels, so access to encrypted information is relatively easily added onto the consumer's telephone bill, providing detailed usage reporting and providing a means for clearing  
20 the smallest payments (i.e. an effective micropayment system, where small individual DRM charges are included within the larger consolidated telephone bill).

In accordance with yet another embodiment, illustrated  
25 in Figure 6, the rights 110 provided from the DRM server 108 are stored on a "smart card" 602, the smart card 602 is used to authenticate the user, or a combination of both. Thus, any DRM-enabled consumer device (such as consumer device 106 and consumer device 206) may employ the rights  
30 to access DRM-encrypted content so long as access to the smart card is provided to the consumer device via a smart card reader 604.

-16-

In accordance with the Figure 6 embodiment, the consumer can now access DRM-encrypted content on any DRM-enabled consumer device on which the smart card can be  
5 read. In addition, the consumer cannot easily make copies of the smart card and thereby defeat the DRM solution. The need for a network connection is minimised or eliminated.

In accordance with the invention, mobile devices are  
10 used to enhance conventional DRM solutions, to accommodate the increasing mobility of DRM users without diminishing (and in some cases, enhancing) the security aspects of the DRM system.

15       Embodiments of the present invention have been described with particular reference to the examples illustrated. However, it will be appreciated that variations and modifications may be made to the examples described within the scope of the present invention.

-17-

CLAIMS

1. A digital rights management (DRM) system governing whether DRM-protected content can be rendered on a content rendering device, wherein at least one rights specification governing access to DRM-protected content on the content rendering device is tied to a first node identifier that is based on a characteristic of a mobile device coupleable to the content rendering device, the system comprising:
- 10 a DRM client arranged to operate within the content rendering device and which has access to the at least one rights specification governing access to the DRM-protected content;
- wherein the at least one rights specification is
- 15 restricted to apply to at least one node identifier;
- the DRM client being arranged to retrieve said characteristic of a mobile device coupleable to the content rendering device, to generate the first node identifier based on said characteristic, and to check that the first
- 20 node identifier matches the or at least one node identifier to which the at least one rights specification is restricted;
- wherein access to the DRM-protected content by the content rendering device is granted subject to the at least
- 25 one rights specification available to the DRM client and subject to the first node identifier matching the or at least one node identifier to which the at least one rights specification is restricted.
- 30 2. A system according to claim 1, wherein the DRM client is arranged to deny access when the mobile device is not coupled to the content rendering device.

-18-

3. A system according to claim 1, wherein the DRM client is arranged to deny access to DRM-protected content after a configurable time period elapses after the DRM client  
5 detects that the mobile device is no longer coupled to the content rendering device.

4. A system according to any of claims 1 to 3, wherein  
the mobile device is a smart card that is readable by a  
10 smart card reader coupled to the content rendering device.

5. A system according to any of claims 1 to 3, wherein the mobile device has a wireless networking capability.

15 6. A system according to claim 5, wherein the first node identifier for the mobile device is based on a network address of the mobile device.

7. A system according to claim 5 or claim 6, wherein the  
20 DRM client is arranged to receive a trusted clock by way of the mobile device.

8. A system according to any of claims 5 to 7, wherein the DRM client is arranged to obtain at least one rights  
25 specification from a DRM server by way of the mobile device.

9. A system according to any of claims 5 to 8, wherein the DRM client is arranged to relinquish at least one  
30 rights specification to a DRM server by way of the mobile device.

-19-

10. A system according to any of claims 5 to 9, wherein the DRM client is arranged to send auditing information to a DRM server by way of the mobile device.

5 11. A method of accessing digital rights management (DRM) protected content for rendering by a content rendering device, wherein at least one rights specification governing access to the DRM-protected content on the content rendering device is tied to a first node identifier that is  
10 based on a characteristic of a mobile device coupleable to the content rendering device, the at least one rights specification being restricted to apply to at least one node identifier, the method comprising the steps of:

retrieving from a mobile device coupled to the content  
15 rendering device said characteristic of the mobile device coupled to the content rendering device;

generating the first node identifier based on said characteristic; and,

checking that the first node identifier matches the or  
20 at least one node identifier to which the at least one rights specification is restricted;

wherein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification available to the DRM client and  
25 subject to the first node identifier matching the or at least one node identifier to which the at least one rights specification is restricted.

12. A method according to claim 11, wherein access to the  
30 DRM-protected content is denied when the mobile device is not coupled to the content rendering device.

-20-

13. A method according to claim 11, wherein access to the DRM-protected content is denied after a configurable time period elapses after the mobile device is no longer coupled to the content rendering device.

5

14. A method according to any of claims 11 to 13, comprising the step of obtaining the at least one rights specification from a DRM server by way of the mobile device.

10

15. A method according to claim 14, comprising the step of storing the at least one rights specification on the mobile device such that the at least one rights specification can be obtained on demand from the mobile device without

15 requiring the mobile device to connect to the DRM server.

16. A method according to any of claims 11 to 15, comprising the step of relinquishing the at least one rights specification to a DRM server by way of the mobile  
20 device.

17. A method according to any of claims 11 to 16, comprising the step of sending auditing information to a DRM server by way of the mobile device.

25

18. A digital rights management (DRM) system governing whether DRM-protected content can be rendered on a content rendering device, wherein at least one rights specification governing access to DRM-protected content on the content  
30 rendering device is obtained from a mobile device coupleable to the content rendering device, the system comprising:

-21-

a DRM client arranged to operate within the content rendering device that is to retrieve from the mobile device the at least one rights specification applying to the DRM-protected content which the content rendering device is  
5 attempting to render;

wherein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification obtained by the DRM client from the mobile device.

10

19. A system according to claim 18, wherein the at least one rights specification obtained from the mobile device is tied to the node identifier of the mobile device, thereby preventing the at least one rights specification from being  
15 obtained from another mobile device.

20. A system according to claim 18 or claim 19, wherein the mobile device contains a tamper-proofing mechanism to prevent unauthorised access to the at least one rights  
20 specification.

21. A system according to any of claims 18 to 20, wherein the DRM client on the content rendering device and the mobile device are arranged to use a challenge-response  
25 protocol to establish trust between them.

22. A system according to any of claims 18 to 21, wherein the DRM client is arranged to deny access to the DRM-protected content after a predetermined time period elapses  
30 after the DRM client detects that the mobile device is no longer coupled to the content rendering device.

-22-

23. A system according to any of claims 18 to 22, wherein the mobile device is a smart card that is readable by a smart card reader coupled to the content rendering device.

5 24. A system according to any of claims 18 to 22, wherein the mobile device has a wireless networking capability.

25. A system according to claim 24, wherein the DRM client is arranged to establish a consumer identity based upon a  
10 network address of the mobile device.

26. A system according to claim 24 or claim 25, wherein the DRM client is arranged to receive a trusted clock by way of the mobile device.

15

27. A system according to any of claims 24 to 26, wherein the DRM client is arranged to obtain at least one rights specification from a DRM server by way of the mobile device.

20

28. A system according to any of claims 24 to 27, wherein the DRM client is arranged to relinquish at least one rights specification to a DRM server by way of the mobile device.

25

29. A system according to any of claims 24 to 28, wherein the DRM client is arranged to send auditing information to a DRM server by way of the mobile device.

30 30. A method of accessing digital rights management (DRM) protected content for rendering by a content rendering device, wherein at least one rights specification governing access to DRM-protected content on the content rendering

-23-

device is obtained from a mobile device coupleable to the content rendering device, the method comprising the steps of:

retrieving from the mobile device the at least one  
5 rights specification applying to the DRM-protected content which the content rendering device is attempting to render;  
wherein access to the DRM-protected content by the content rendering device is granted subject to the at least one rights specification obtained from the mobile device.

10

31. A method according to claim 30, wherein the at least one rights specification obtained from the mobile device is tied to the node identifier of the mobile device, thereby preventing the at least one rights specification from being  
15 obtained from another mobile device.

32. A method according to claim 30 or claim 31, wherein access to the DRM-protected content is denied after a predetermined time period elapses after the mobile device  
20 is no longer coupled to the content rendering device.

33. A method according to any of claims 30 to 32, comprising the step of obtaining the at least one rights specification from a DRM server by way of the mobile  
25 device.

34. A method according to claim 33, comprising the step of storing the at least one rights specification on the mobile device such that the at least one rights specification can  
30 be obtained on demand from the mobile device without requiring the mobile device to connect to the DRM server.

-24-

35. A method according to any of claims 30 to 34, comprising the step of relinquishing the at least one rights specification to a DRM server by way of the mobile device.

5

36. A method according to any of claims 30 to 35, comprising the step of sending auditing information to a DRM server by way of the mobile device.

10 37. A digital rights management (DRM) system for managing access to content on a content rendering device that is coupled to a wireless device that is coupled to a wireless network, wherein usage of the wireless device on the wireless network produces billing information that is  
15 accounted for by a billing system, the system comprising:  
a DRM server for coupling to a said wireless network and arranged to provide at least one rights specification for gaining access to content on a said content rendering device, the DRM server being arranged to account for usage  
20 of the DRM-protected content and to provide billing information based on the usage of the DRM-protected content to a said billing system, such that the said billing system can consolidate billing information based on the usage of the DRM-protected content with billing information based on  
25 the usage of the wireless device.

38. A system according to claim 37, wherein the billing information based upon the usage of the DRM-protected content is the basis for a micro-payments system.

Fig.1.

## DRM OVERVIEW (PRIOR ART)

2. The rights are stored on node A's persistent storage. The use of the rights involves A's DRM client re-obtaining or re-calculating the node identifier and checking that it matches the value to which the rights are locked.

1. Rights are transferred from DRM server to node A. As part of the transaction the rights are locked to a semi-unique identifier obtained or calculated from characteristics of node A.

3. Transferring the node-locked rights to another node (say B) renders it ineffective since, depending upon the nature of the node identifier, there is very little chance that B's node identifier will match A's.

Fig.2.  
BASIC NODE-LOCK CONCEPTS

1. Rights are transferred from DRM server to device X (to which mobile device A is docked). As part of the transaction the rights are 'locked' to a semi-unique identifier obtained or calculated from characteristics of mobile device A.

2. The rights are stored on device X's persistent storage. The subsequent use of the rights involves X's DRM client re-obtaining and re-calculating the node identifier from any attached mobile device and checking that it matches the value to which the rights are 'locked'.

3. Transferring the mobile node-locked rights to another device (say Y) will only be effective if the original mobile device, A, is also transferred and docked to Y so that Y's DRM client can match its node identifier to that of the rights.

Fig.3.

PORTABLE DEVICE LOCK-AUTHENTICATION

Fig.4.

PORTABLE DEVICE LOCK - STORAGE

1. Rights are transferred from DRM server to device X (to which mobile device A is docked). As part of the transaction the rights are 'locked' to a semi-unique identifier obtained or calculated from characteristics of mobile device A.

2. The rights are stored on the mobile device A. Subsequent use of the rights involves X's DRM client re-obtaining and re-calculating the node identifier from the attached mobile device, checking that it matches the stored rights and accessing the rights from the mobile device.

3. As the rights are now stored on the mobile device, and 'locked' to that device, it may only be accessed from device Y by undocking the mobile device from X and docking it to Y.

4. Rights may also be copied / transferred on secondary removable storage such as floppy discs, flash RAM, SIMs, etc readable on either device.

**Fig.5.**  
PHONE LOCK

But : telephone equipped mobile device can also:

- (a) Maintain a trusted clock signal from a central server
- (b) Itself connect to the DRM server to obtain, refresh or relinquish rights
- (c) Piggyback DRM traffic on regular background cell communications
- (d) Provide integrated billing/micropayment with cellular telephony billing

1. Rights are transferred from DRM server to device X (to which mobile device A is docked). As part of the transaction the rights are 'locked' to a semi-unique identifier obtained or calculated from characteristics of node device A.

2. The rights are also stored on the mobile device A. Subsequent use of the rights involves X's DRM client re-obtaining and re-calculating the node identifier from the attached mobile device, checking that it matches the stored rights and accessing the rights from the mobile device.

3. As the rights are now stored on the mobile device, and 'locked' to that device, it may only be accessed from device Y by undocking the mobile device from X and docking it to Y.

4. Rights may also be copied/ transferred on secondary removable storage such as floppy discs, flash RAM, SIMs, etc readable on either device.

But : counterfeit - proof 'smart' cards

- either :
- (a) Authenticate consumer to client and / or server-based DRM systems
  - (b) Store rights for off-line access via a smart-card reader attached to the consumer device

SMART CARD LOCK

# INTERNATIONAL SEARCH REPORT

International Application No

PCT/GB 01/02853

## A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 G06F1/00

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G06F H04N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data, PAJ

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	EP 1 081 616 A (MATSUSHITA ELECTRIC IND CO LTD) 7 March 2001 (2001-03-07)  page 7, line 11 - line 31 page 8, line 20 - line 26 page 8, line 35 - line 49 page 11, line 33 - line 45	18,20, 22,30, 33,34

☒ Patent family members are listed in annex.

### \* Special categories of cited documents:

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

\*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone.

\*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

\*G\* document member of the same patent family
